Promoting Rule Compliance in Daily-Life: Evidence from a Randomized Field Experiment in the Public Libraries of Barcelona^{*}

First Draft: August 2010 This Draft: August 2012

Abstract

We study how to promote compliance with rules that carry low penalties and are pervasive in all sorts of organizations. We have access to data on the users of all public libraries in Barcelona. In this setting, we test the effect of sending email messages with different contents. We find that users return their items earlier if asked to do so in a simple email, showing that a general reminder of the users' duty is effective in promoting rule compliance. Furthermore, adding other contents to the general reminder does not increase compliance significantly. **Keywords:** Rule Compliance, Field Experiment, Public Libraries. **JEL classification numbers:** C93, D01, D03, D63, K42.

^{*}We are grateful to Anna Surroca (*Serveis de Biblioteques of the Diputacio de Barcelona*), Judit Terma (*Consorci de Biblioteques de Barcelona*), and their respective teams, for their collaboration and assistance in conducting this study. We thank Antonio Cabrales, Pablo Casas, Vincent P. Crawford, Laura Gee, Rosemarie Nagel, Imran Rasul, Pedro Rey-Biel, Carmit Segal, Alessandro Tarozzi, Christian Traxler and seminar participants at Erasmus University Rotterdam, Universidad de Alicante, University of East Anglia, University of Essex, University of California San Diego, Universidad Carlos III, University of Granada, University of Mannheim, Paris School of Economics, University of Pittsburgh, Universitat Pompeu Fabra, University Rome Tor Vergata, and Stockholm University for helpful comments. Special thanks go to Stephan Litschig for constant feedback and discussions. Sergio Correia provided excellent research assistance. Financial support from the Spanish Commission of Science and Technology (ECO2008-01768, ECO2009-12836, ECO2009-11213 and SEJ2007-64340), and Fundación Rafael del Pino is gratefully acknowledged.

1 Introduction

Understanding compliance with rules is crucial for firms, organizations, and societies at large. While some rules are backed by severe sanctions, there are many others with relatively low punishment. To illustrate, workers are supposed to attend meetings, to obey certain working hours, to respect the lunch breaks, to follow certain dress codes, to respect the rules on how to interact with customers, employees and managers, on how to answer phone calls, on how to report productivity, etc. All these examples constitute rules where there is usually no monetary penalties attached with rule breaking. While these rules are pervasive and important for the functioning of organizations and societies, very little is known on how to promote compliance with them.

In this paper we contribute towards a better understanding of the mechanisms that may promote compliance with these types of rules. While economists would naturally think about monetary incentives, it has been found that they may backfire (see Benabou and Tirole, 2003 and 2006, for theoretical arguments; Gneezy and Rustichini, 2000a and 2000b, and Mellstroem and Johannesson, 2008, for empirical studies), or that they are not feasible due to political or legal restrictions. Therefore, it is crucial to understand whether there are other possible ways to promote compliance with rules. The goal of this paper is to analyze the effect of conveying various types of messages, in our case by email. Our interest in the potential effects of sending messages is that it offers a virtually costless and non-invasive intervention mechanism that is simple and flexible to implement. Surprisingly, despite the advantages of this message intervention, little is known about its effectiveness.

A setting that allows us to study compliance with rules with low penalties is the Network of Public Libraries in the city of Barcelona. The type of compliant behavior we analyze is whether users of the libraries return the items they borrowed on time. A user not returning an item by the due date is violating the rule, and generating a negative externality on the population of users. The penalty associated with returning an item late does not involve any monetary fines, but the exclusion from the possibility of borrowing more items for a time period equal to the number of days the item is overdue. We evaluate whether we can get users to return the items they borrow earlier, by means of different email contents that are randomly allocated.

There are important characteristics that make our study unique. First, we observe

the borrowing behavior of all users of all public libraries in Barcelona over eleven months. During this time span, there were about 50,000 different users, who borrowed over a million items in the 32 different libraries spread throughout the city of Barcelona. Therefore, we have data on a large number of individuals, in a daily-life situation, taking part in their natural environment, and over an extended period of time. Second, we observe *every* borrowing-returning transaction of items made by users. This allows us to measure compliant behavior with the borrowing rules with exact precision. Third, the rules that govern the interaction between the users and the libraries are simple and well-defined. Finally, the rich data on users offers a unique opportunity to test for differential treatment effects with regard to previous compliance and demographic variables such as gender, age, and nationality.

We randomize all users into groups receiving one of five different email messages, and study their behavior after receiving the email. One of the five email messages is a CONTROL message that provides a link to the webpage of the Network of Libraries. All the remaining messages add content to the text in CONTROL. The first treatment message, called REMINDER, represents a general reminder of the users' duty to return the borrowed items on time. The second message, SOCIAL, adds to REMINDER an appeal to the effect individual behavior can have on the overall functioning of the public library services. The last two email treatments, LATE and PENALTY, are targeted only at those users who have recently returned at least one item late. Both LATE and PENALTY add to REMINDER the identification of the user as having recently returned items late. Finally, PENALTY builds on LATE and adds a reminder of the penalty associated with non-compliant behavior. Therefore, our email messages are designed to evaluate whether a generic reminder promotes rule-compliance and whether adding contents related to social motivations, the explicit identification for being late, or directing the attention of users towards the penalties associated for rule-breaking, make users conform with the rule to a greater extent.

In our analysis we evaluate the effect of emails on the proportion of late returned items by user, and on the number of days that elapse between the return date and the due date. The first variable measures the propensity to comply with the rule, while the second variable quantifies the positive/negative externality that is imposed on other users when a user returns the item earlier/later than the due date. Our main result is that compliant behavior can be promoted by sending an email that includes a general reminder of the users' duty to comply with the rule. All four treatment emails significantly reduce both, the proportion of late returned items, and the number of days between the return date and the due date. The treatments reduce the proportion of late returned items by up to 10 percent and the number of days between the return and the due date by up to almost one day. These effects are not only statistically significant but also economically relevant, especially in light of the negligible costs associated with the intervention. Furthermore, we cannot reject the hypothesis that all four different contents have the same effect, showing that the additional contents to the general reminder do not increase rule compliance significantly.

As for the effectiveness over time, we show that the effect of getting one of these emails is short-term, mostly significant in the few weeks after the treatment. However, the effect is reproduced when the same email is received for a second time, in our case two and a half months later. As such, our results suggest that sending multiple emails can help to keep compliance high.

With regard to heterogeneous treatment effects, we find that users with a higher proportion of late returns in the pre-treatment period react more strongly than users with a lower proportion of late returns. Interestingly, even the "good citizens" react positively to receiving an email. Hence, the email treatment is more effective precisely with those users whose compliance prior to the treatment was lower, and, importantly, does not generate crowding-out effects in those users that were complying with the rule before the intervention.

A natural interpretation of our results is that individuals pay limited attention to the duty to return items on time, and an email reminding them about this duty increases rule compliance (see Karlan et al., 2011, for a model of limited attention, and empirical evidence supporting it). This interpretation is consistent with our main results. Adding extra messages to the reminder email does not significantly change behavior, and precisely those users who were complying the least are the ones that react the most. An alternative interpretation of our results is that users interpret the treatment emails as a signal that the libraries care about rule compliance (maybe to a greater extent than expected), and that this triggers a positive reaction on them. According to this interpretation, users react to their beliefs about what the authorities expect from them. Although the result that a simple reminder increases rule compliance has important implications for organizations and authorities, future research should be directed to disentangle among the two possible interpretations given above.

Last, we investigate differences in reactions according to user demographics. With respect to gender, we find no significant differences in reactions to the treatments between women and men - despite evidence on gender differences in other economically relevant situations (see Croson and Gneezy, 2009). In terms of age, we do not find any consistent differences across age groups in the reaction to the treatments either. As for users' nationalities, we study reactions of users from different geographical regions. Consistent with Fisman and Miguel (2007), we find different reactions depending on the users' nationalities. Interestingly, only Spaniards, people from English speaking countries and Asians react to the emails.

Our paper is one of the first to study the effect of messages on compliance with rules. There is a literature showing that allowing for free communication between interacting agents before they take actions changes outcomes in specific experimental settings that broadly relate to pro-social behavior, such as hold-up problem games (Ellingsen and Johannesson, 2004), trust games and hidden-information games (Charness and Dufwenberg, 2006 and 2011) and dictator games (Ellingsen and Johannesson, 2008; Andreoni and Rao, 2010). However, relatively little is known about the effect of *specific message contents* on promoting pro-social behavior and compliance with rules.

The paper also differs from a strand of literature that investigates how providing information affects various individual choices such as retirement decisions (Duflo and Saez, 2003), or school choices (Jensen, 2010). These settings study the effect of providing information on very complex goods and services, whose characteristics are most likely only partially known by the individuals. In contrast, we study a familiar and everyday scenario where there is a simple and well-defined rule, which is known by the users. Consequently, it is less clear whether information will have any effect in this situation.

Studying compliance in public libraries by way of the random allocation of messages, we add to a small but growing literature on the influence of messages in other settings. First, there is work that studies the effect of messages on *norm* compliance. Schultz et al. (2007) and Ayres, Raseman and Shih (2009) show that home electricity consumption can be reduced when households get periodic reports on the consumption of comparable neighbors. Karlan et al. (2011) show that when individuals are reminded of their previous saving commitments, the likelihood of reaching their saving goal increases (see also Kast, Meier and Pomeranz, 2012, for a similar result). Gerber, Green and Larimer (2008) and Dale and Strauss (2009) have found that text messages increase the probability of voting of registered voters. Huck and Rasul (2010) show that sending reminding letters in fundraising campaigns is effective. Dal Bó and Dal Bó (2010) conducted a series of laboratory two-player public good experiments to study the influence on individual contribution levels when players receive a message appealing to moral rules. Finally, there are also papers studying the effect of reminders on adherence to health care recommendations like vaccinations (see, e.g., the recent editorial of Szilagyi and Adams, 2012, in the JAMA). The main difference between these studies and ours is that in our case there is an exogenously imposed rule that dictates clearly what to do, namely to return the items on time, as opposed to recommendations, or some unwritten, informal, or self-imposed norm. This is important since it has been shown that in many contexts behavior varies depending on whether it is regulated by internal norms or externally imposed rules (see Ostrom, 1990; Crawford and Ostrom, 1995). In particular, there is evidence that compliance with self-imposed norms is much higher than compliance with exogenously imposed rules, even when these are comparable in the final desired behavior and associated penalties (see Dal Bó, Foster, and Putterman, 2010, for recent experimental evidence). Therefore, the literature on the effect of messages on behavior regulated by norms is not necessarily informative for the library setting investigated here.

Second, three related papers analyze the effect of messages on individual compliance with rules. Pomeranz (2010) analyzes firms' tax compliance in Chile, Fellner, Sausgruber, and Traxler (2011) study citizens' subscriptions to TV licenses in Austria, and Cadena and Schoar (2011) analyze loan-repayments in Uganda. In contrast to these studies, our setting includes a formal rule with relatively low penalty. What to expect a priori from the email intervention when stakes are small is open to question, since users may simply ignore the messages they receive.¹ Our paper additionally differs in that we can perfectly measure compliance with rules, and study the effect of messages on different users on the basis of their previous compliance. This is important because there is evidence on crowding out effects of different interventions on individual

¹That stakes matter is quintessential to Economics. For recent examples related to rule and norm compliance, where the relation between stakes and behavior is non-trivial, see Gneezy and Rustichini (2000a) and Andersen et al. (2011).

behavior (see Frey and Jegen, 2001).

The remainder of this paper is organized as follows. Section 2 describes the setting, namely the Network of Public Libraries in the city of Barcelona, and explains the design of the field experiment, as well as the identification strategy. Section 3 is devoted to the presentation and discussion of the results. Finally, Section 4 concludes.

2 The Field Experiment

2.1 The Setting: Network of Public Libraries of Barcelona

The Network of Public Libraries in the city of Barcelona is managed by a central body dependent on the City Hall of Barcelona and the Government of the Province of Barcelona. It encompasses 32 libraries spread throughout the city of Barcelona. Each library offers the possibility of borrowing items such as books, DVDs, CDs and magazines; other services such as internet access and exhibitions are also provided.

The rules governing the borrowing of different item types are clearly defined and are the same for all the 32 libraries. At the time of our study, a book could be borrowed for 21 days, while all other item types (DVDs, CDs and magazines) could be borrowed for 7 days. Users could also ask to extend the due date if no other user required that item. As for the maximum number of items to be taken, each user could simultaneously take a total of 30 items, 15 books and magazines, and 15 CDs and DVDs. The penalty associated with returning an item late involved being barred from borrowing new items for a time period equivalent to the number of days elapsed between the due date and the actual return day. In particular, there was no monetary fine associated with not complying with the return policy.

2.2 Data and Email Contents

We observed the complete borrowing/returning behavior for every single user from January 2009 until the beginning of November 2009.² For every transaction we observed (i) the user code, gender, age, and nationality, (ii) the item code and its characteristics,

 $^{^{2}}$ Libraries offer other services, like reading rooms or free internet access. Our study focuses on rule compliance regarding borrowing/returning behavior, but we do not observe or analyze possible interactions between this type of rule compliance and other behaviors.

that is, whether it was a book, DVD, CD, or magazine, (iii) the dates of the transaction, that is, the date when the item was borrowed and returned, and (iv) the library where the transaction took place. With this information we were able to follow the exact borrowing behavior of every single user of the Network of Public Libraries in Barcelona. Given that our design is based on emails, we concentrate on the sample of those users with a known email.³ This gives us about 50,000 different users, who borrowed over a million items.

The Network of Public Libraries in the city of Barcelona maintains constant communication with its users via email. Most emails include information on the activities organized in the different libraries of the city, such as exhibitions, and on opening hours. In collaboration with the Network, we designed five different email messages (see Table 1) that were randomly assigned to the users.⁴

[Table 1 here]

CONTROL refers to the control treatment. It provides a link to the webpage of the Network of Public Libraries. The rationale for this treatment is that by comparing the effect of the other treatment messages relative to the CONTROL, we are able to differentiate the effect of the content of a treatment message from that of just getting an email from the Network of Libraries. The rest of the treatment messages build on CONTROL, adding different pieces of information. REMINDER represents a general reminder of users' duty to return items on time. There is evidence that people fail to pay attention to all the relevant contingencies they are involved in (see Karlan et al., 2011; Szilagyi and Adams, 2012). In this sense, mechanisms calling the attention of individuals to a specific margin may improve their behavior related to it. REMINDER, then, aims to test whether by simply recalling the duty of returning the items on time improves behavior towards it. SOCIAL builds on REMINDER, adding an appeal to the influence of individual behavior on the proper overall functioning of the public system of libraries. There is a large literature in Economics showing that individuals often care about the well-being of others, even when this comes at a personal cost (see, e.g., Andreoni and Miller, 2002; Charness and Rabin, 2002; Sobel, 2005). The purpose of

 $^{^{3}}$ The Network of Public Libraries knows the email addresses of around 40% of the registered users.

⁴The subject lines of all the five email messages contained the same text: "Important Notice." By writing so in the subject line we aimed to distinguish our emails from the ones users receive regularly.

SOCIAL is to test whether an appeal to the influence of one's behavior on the others improves rule compliance on top of the simple reminder. Email LATE adds to the content of REMINDER a statement that identifies the user as having recently returned an item late. It has been shown (see Gerber, Green and Larimer, 2008) that explicitly revealing that one has been observed breaking a norm reduces the norm breaking. This may be due to triggering feelings of guilt or shame (see, e.g., Battigalli and Dufwenberg, 2007). Then, the purpose of LATE is to test whether the explicit mentioning of having been observed as a non-compliant improves behavior. Finally, PENALTY builds on LATE adding a reminder of the actual penalty associated with returning an item late. Here, we aim to direct users' attention to their own cost when breaking the rules. Our inspiration is the large literature in Law and Economics on the deterrence effect of punishment (see Becker, 1968). The purpose here is to evaluate whether focusing the attention of users towards the penalties improves rule-compliance on top of LATE.

It has been our aim to design emails with general contents that could be applied to many settings of interest beside libraries. For this reason, no email makes any reference to particular items that may have been borrowed at the time of receiving the email. Moreover, not all settings permit the type of precise data on individual behavior that we had at the moment of treatment (e.g., identifying users as late and non-late). In this vein, three of our emails, CONTROL, REMINDER and SOCIAL, are general in the sense of not using any information on the behavior of users prior to the treatment, and can therefore easily be adapted to other settings. In the context of firms, one can think of rules governing the interaction between employees and customers, where employees' behavior is not perfectly observable to the managers. On top of that, for cases where information on individual behavior is available to the policy maker, it is important to analyze potential effects of using such specific information. In our case, LATE and PENALTY use information on user history in order to directly target non-compliant individuals. For examples within firms, for those workers who did not attend meetings or arrived late, messages could include specific references to their behavior in the past.

2.3 Randomization

We sent emails in two different waves. Wave 1 was sent on July 1st, 2009, when we reached about 36,700 users. Wave 2 was sent on September 15th, 2009, when we

reached about 38,300 users. Overall, we reached about 50,000 different users.⁵

In Wave 1 (resp. Wave 2) we considered all the active users between January 1st and May 5th, 2009 (resp. between March 1st and July 31st, 2009), and classified them into two categories: late users and non-late users. An active user is a user who borrowed at least one item during the time interval mentioned. A late user is a user who returned an item after the due date at least once during the time interval. A non-late user is a user who did not return any item late during the time interval. Late users were randomly assigned to the five different treatments, while non-late users were randomly assigned to CONTROL, REMINDER and SOCIAL only.⁶ The randomization was carried out at the user level and in order to ensure balance across different libraries, we stratified the randomization using the library at which users signed up.

Note that in Wave 2 we have users who were already active in Wave 1 and new active users, namely those users who were active only between May and July. With regard to the new active users, we repeated the randomization procedure as in Wave 1. The active users in Wave 2 who were also active in Wave 1 received exactly the same email as in Wave 1.⁷ Exceptions were those users who were allocated to LATE or PENALTY in Wave 1 but who, during the interval between March 1st 2009 and July 31st 2009, were never late again. There were about 700 of such users, who were excluded from the randomization, and hence received no email in Wave 2.

Table 2 reports the descriptive statistics of all users, both non-late and late, who were randomly assigned to treatments CONTROL, REMINDER and SOCIAL in Waves 1 (top) and 2 (bottom). Table 3 reports the descriptive statistics of late users only, randomly assigned to the five treatments in Waves 1 (top) and 2 (bottom). Note that late users in CONTROL, REMINDER and SOCIAL appear in both tables. The last column in Tables 2 and 3 report the *p*-values for the *F*-Test of equality of variable means across all groups.

[Tables 2 and 3 here]

 $^{{}^{5}}$ In each wave we sent about 50,000 emails but not all emails were actually delivered. About 30% of email addresses turned out to be invalid and the email messages were returned to the server as messages that were never delivered. We therefore restrict our analysis to those users to whom the message was delivered.

⁶There were 21,571 late users and 15,106 non-late users in Wave 1.

⁷There were 10,492 new active users in Wave 2, of which 5,191 were late users and 5,301 were non-late users. There were about 28,500 users who were also active in Wave 1.

Consistent with the random assignment of users to treatments, the average user has similar values in the observable characteristics across the different treatments.⁸

In Tables 2 and 3, we can see the magnitude of the problem of late returns. Considering those users who have been late at least once, around 60% of the loans per user are returned after the due date. Furthermore, the typical late user returns the borrowed items on average 6.5 days later than the due date.

In our analysis, as is standard practice in any randomized field experiment, we concentrate on the post-treatment period, that is, on the behavior of users after the email intervention. For those users who received the email message in Wave 1, the post-treatment starts on the 1st of July. For those users who got the email for the first time in Wave 2, the post-treatment starts on the 15th of September.

Not all users who received the email treatment appear in the post-treatment period; some users neither borrow nor return any item at any time in the post-treatment period. It is important to investigate whether the email treatments affected borrowing behavior, and whether conditional on borrowing, the randomization is still valid. As a first step, we investigate, separately for Waves 1 and 2, the users' probabilities of being active in the post-treatment period, as well as their borrowing intensity measured by the number of loans taken. In particular, we test whether the variables "Active" (a dummy taking a value of 1 if the user borrows/returns any item in the post-treatment period, and 0 otherwise) and "Number of Loans" (which measures the number of loans in the post-treatment period and takes the value of 0 for those users who are not active) show significant differences across treatments.

[Table 4]

As can be seen from Table 4, around 50% of emailed users were active in the posttreatment period (see the constant in columns (1) and (5)), and the number of borrowed items was between 4 and 6 (see the constant in columns (3) and (7)). More importantly, we cannot reject the null that the probability of being active and the number of loans taken is equal between the control and the treatment groups (see *p*-values at the bottom of each column in Table 4). Therefore, the email interventions did neither affect differentially the likelihood of being active, nor the borrowing intensity compared to

⁸An exception is the proportion of foreigners, possibly due to the valid email address correction (see footnote 5). However, the mean values do not show sizable differences.

the control email.⁹ We also study whether the email intervention had any effect on the *types of users* who are active after being treated. To do so, we redid the randomization of Tables 2 and 3 only for those users who were treated and active in the post-treatment period. We find no differences in observable characteristics across the treatments. To summarize, this analysis prevents possible concerns about differential selection into borrowing behavior based on being treated.

2.4 Identification Strategy

We focus on two different dependent variables. First, we look at the proportion of late returned items per user (*Proportion Late*). This is a direct measure of how users comply with the rule. Second, we use the average number of days between the return date and the due date per user (*"Actual-Due" Date*). When this difference is positive (resp. negative) the item was returned late (resp. early) compared to the due date. In contrast to the first dependent variable, which measures late/non-late per item in a binary way, this second variable also takes into account the extent of late or early returns.

In a randomized experiment like ours, the causal effect of the treatments can be estimated as follows:

$$Y_i = \alpha + \beta_1 Reminder_i + \beta_2 Social_i + \beta_3 Late_i + \beta_4 Penalty_i + \epsilon_i$$
(1)

where the dependent variable Y_i is either (i) the proportion of late returns per user, or (ii) the average number of days between the return date and the due date per user.¹⁰ *Reminder_i*, *Social_i*, *Late_i*, and *Penalty_i* are dummy variables taking a value of 1 when user *i* was assigned to REMINDER, or SOCIAL, or LATE, or PENALTY, respectively. The omitted treatment to which these variables are compared is CONTROL.

Consistent with our design, we will estimate equation (1) in two different ways. First, we compare REMINDER and SOCIAL to CONTROL for all users, independent

⁹The fact that around half of the treated users are active in the post-treatment period seems to reflect natural trends over time. When computing comparable *Active* and *Number of Loans* for those users with unknown email, we get similar values.

¹⁰Note that the dependent variables are obtained by collapsing all the transactions at the user level. For example, a user with 5 transactions that was late with 4 of them has a proportion of late returns of 4/5. In the subsequent analysis, when we add control variables, we also collapse them at the user level.

of whether they were late or not in the pre-treatment period. Second, we compare REMINDER, SOCIAL, LATE and PENALTY to CONTROL, restricted to all users who were late at least once in the pre-treatment period.

3 Results

3.1 Average Treatment Effects

We estimate equation (1) by OLS. Table 5 reports the results for CONTROL, RE-MINDER, and SOCIAL, covering all users, both late and non-late users, who got one of these emails in Waves 1 and 2. Table 6 reports the results for all five treatments restricted to the late users only.¹¹ The first four columns in both tables refer to the proportion of late returns per user, while the last four columns refer to the average number of days between the return date and due date per user.

[Tables 5 and 6 here]

We start commenting on the treatment effect on users conditional on borrowing in the post-treatment period (columns (1) to (3) and (5) to (7) in Tables 5 and 6). In both tables the first column reports the results of estimating equation (1) without any controls. The second column controls for users' demographics, such as gender, whether the user is foreign or not, and for different age intervals. It also includes controls for different months between July and November, as well as the number of borrowed items. Finally, in the second column we also add controls for users' behavior prior to the treatment, which measures their propensity for late returns and for the average number of days between the return date and the due date per user, prior to the treatment. The third column adds more controls in addition to all the previous variables, accounting for the item type (whether it refers to a book, DVD, CD or a magazine), as well as library fixed effects.¹²

¹¹The results in Tables 5 and 6 are highly robust with regard to other specifications. If instead of collapsing the data at the user level, we estimate random effects with transaction level data, the results we obtain are both qualitatively and quantitatively similar.

¹²In all specifications, we discard transactions that were due on a holiday, when the library was closed.

In Table 5, both REMINDER and SOCIAL are significant and negative, showing that both email treatments significantly reduce the proportion of late returns and the number of days between the return date and the due date. Taking the estimates of the third column, receiving a REMINDER email decreases the proportion of late returns by 1.4 percentage points (compared to CONTROL), and 1.8 percentage points in the case of SOCIAL. Evaluated at the mean propensity of being late for the control group (approximately 36 percent), the reduction in late returns lies between 4 percent (REMINDER) and 5 percent (SOCIAL). Moreover, receiving a treatment email also significantly decreases the number of days between the return date and the due date: the REMINDER and SOCIAL emails decrease this difference on average by almost half a day with respect to CONTROL. Note also that the coefficients of the REMINDER and the SOCIAL emails are not statistically different from each other, meaning that the appeal to social preferences, through one's contribution to the functioning of public libraries, did not affect users' behavior differently from the general reminder.

Focusing on previously late users (Table 6), we see that all four email treatments are negative and significant; both for the proportion of late returns per user and for the average number of days between the return date and the due date per user. For instance, from column (3) we see that the treatment effects (compared to the control) range from -2.4 percentage points for the REMINDER to -4.3 percentage points for the PENALTY. As for the number of days between the return date and the due date, the reduction lies between 0.54 and 0.87 days. Evaluated at the means of the control group, the treatment effects correspond to a reduction in the proportion of late returns up to 10 percent, and a reduction of over 100 percent for the number of days between the return and the due date.¹³ Concerning differences in the messages' effectiveness, we cannot reject the hypothesis that all four email contents affect users' behavior in an equal manner. That is, a general reminder of the users' duty to comply with the rule is enough to promote rule compliance, and the additional contents of the other email messages, using appeals to one's contribution on the functioning of public libraries or identifying users as having been late, do not additionally affect behavior. One qualification concerns the penalty treatment: in the specification with proportion late

 $^{^{13}}$ The mean of the control group in the post-period is 0.44 for the proportion late (see the constant in column (1)), and 0.759 for the number of days between return and due date (see the constant in column (5)).

as a dependent variable, the pairwise significance test reveals a higher effectiveness of the penalty treatment compared to the general reminder. Nevertheless, there is certainly no strong evidence that the different messages affect behavior in a different way.¹⁴

Columns (4) and (8) in Tables 5 and 6 show the estimates for the treatment effects using an intent-to-treat approach. These intent-to-treat estimates are smaller in magnitudes, which is to be expected given that they measure the effect of the messages on late returned items of *all* treated users, irrespective of being active or not. The estimates are still negative and significant, with one exception (REMINDER in Table 5 for the variable *Proportion Late*). Moreover, we cannot reject the hypothesis that all email contents affect users' behavior in an equal manner. Since there is no evidence that messages affected borrowing behavior differentially (see Table 4 and the discussion on pages 11 and 12), we from now on focus on treatment effects conditional on borrowing.

We now proceed with a finer analysis to shed light on the mechanism behind the average treatment effects. Note first that at the time of receiving the email, there are two types of users: those who have an open balance, that is, a borrowed item from the library, and those who have a closed balance (no borrowed items at the time of the email intervention). To better understand whether the aggregate effect mainly comes from open balances, or whether the email messages also affect timely returns in users' later transactions, we analyze these two types of transactions separately.

[Table 7 here]

Table 7 reports the results when splitting up the data into open and closed transactions. To save on space, we only report estimates including the full set of controls and library fixed effects from now on. We first comment on the results for the users who were randomized into the treatments CONTROL, REMINDER and SOCIAL (columns (1), (2), (5) and (6)). As can be seen therefore, the coefficient estimates are quite similar for open and closed transactions, when *Proportion Late* is the dependent variable. For the

¹⁴We have also looked at other dependent variables of interest, such as, $Any \ Late$, which takes a value 1 if a user was late at least once in the post-treatment period and 0 otherwise, and Days*Outstanding*, which measures the number of days the item is returned with delay. We find qualitatively similar results with the exception that the PENALTY email seems to be slightly more effective when restricting to late users only.

variable "Actual-Due" Date, the treatments are more effective for open transactions. When analyzing previously late users (columns (3), (4), (7) and (8)), we see that all treatments are negative and significant for both the open and closed transactions.¹⁵ Again, we find that the treatments are comparable for the dependent variable *Proportion Late*, but slightly more effective for open balance transactions when the dependent variable "Actual-Due" Date is used.

We conclude that, overall, the average treatment effects in Tables 5 and 6 were not only generated from the loans that were open and pending at the time of the email intervention; instead, the treatments affected all users' behavior, also the behavior of those users who had a closed balance at the time of the email intervention. This is important to understand when we think of the applicability to other settings, as to whether the target population consists of individuals who are currently subject to the rule or also those who may be in the future.

3.2 Duration of the Treatment Effect

Having shown that receiving an email has a significant effect on behavior, we now address the question related to the duration of the effect. To this end, we partition the post-treatment period into 8 different time windows: (i) July 1-14, (ii) July 15-31, (iii) August 1-14, (iv) August 15-31, (v) September 1-14, (vi) September 15-30, (vii) October 1-14, and (viii) October 15-onwards. Furthermore, to facilitate interpretation of the results, we restrict the analysis to users who get two emails. With the sample of users being fixed, one can easily distinguish between the effect of the first and the second email.¹⁶

Table 8 reports the estimates for equation (1) separately for the eight time windows. The first page of Table 8 refers to treatments CONTROL, REMINDER, and SOCIAL, covering all users, while the second page of Table 8 reports the results for all five

¹⁵We have further investigated the effect of emails on transactions which are open and due (which include few observations). Since these users are already late, the relevant dependent variable is "Actual-Due" Date. We do not find any significant effect.

¹⁶We also analyzed whether the effect on users who get two emails is significantly different from the effect on users who get only one email. We find that for the proportion of late returns, the effect is larger for users who get two emails. We find no significant differences for the dependent variable "Actual-Due" Date.

treatments (restricted to previously late users only).

[Table 8 here]

The tables show that the effect of getting an email is short term, but it is replicated after getting a second email. No matter whether we use the proportion of late returns per user as a dependent variable, or the average number of days between the return date and the due date, the effect is negative and mostly significant in the short-term. The first emails that were sent on July 1 had an effect in the period July 1-14 and some of the treatments also in the period July 15-31, but the effect becomes insignificant afterwards. A similar pattern can be observed for the emails that were sent on September 15, even though the effects seem to last a bit longer here. Furthermore, for most email messages (see bottom of Table 8), we cannot reject the null that treatments are the same in the first and the sixth time window. Therefore, users who stopped reacting to the first email react again upon reception of the second message, in a comparable manner.¹⁷

3.3 Heterogenous Treatment Effects by User Characteristics

After estimating the average treatment effect of sending different emails, we now proceed to the analysis of heterogeneous reactions depending on relevant user-specific characteristics. We start testing for differential treatment effects that depend on users' previous behavior. Afterwards, we study whether there are significant differences in behavior depending on gender, age and nationality.¹⁸

3.3.1 Previous Compliance with the Rule

It is conceivable that the reaction to the different treatments is related to the users' compliance history, that is, their behavior prior to the treatment. To test for this, we interact the treatment variables with two new variables: *Prior Late* and *Prior "Actual-Due." Prior Late* and *Prior "Actual-Due"* refer to the average user-specific

¹⁷We also did this analysis separately for the open and closed transactions. Interestingly, the effect in the first email is mostly coming from the open transactions at the time of the email intervention, while the effect in the second email is mostly coming from closed transactions at the time of receiving the second email.

¹⁸We also investigated other differential treatment effects that depend on the number of borrowed items as well as the borrowed item types. We did not find any significant differences.

proportion of late returns and days between return and due date in the pre-treatment period, respectively.

[Table 9 here]

Table 9 reports the results. We observe that the significant interaction terms are negative, suggesting that when there is a differential treatment effect by the less rulecompliant users, they react more strongly. In particular, when the treatment variables are interacted with the user-specific *Prior "Actual–Due"* (columns (2) and (4)), we see that the previous non-compliers have a stronger reaction to the REMINDER message, but also to the LATE and PENALTY messages.

To summarize, the email treatments are especially effective in changing the behavior of a very relevant sample of users, namely those breaking the rule more often. Also, it is important to see that there are no crowding out effects. For users who have a value of *Prior Late* and *Prior "Actual–Due"* equal to 0, the estimated treatment effects are still negative (some of them significant), suggesting a positive effect on the "good types" as well.

3.3.2 Gender, Age and Nationality

We focus on three demographic variables: users' gender, age and nationality. Table 10 shows the treatment effects for male and female users, for different age groups and for different nationalities. The first page of Table 10 refers to the treatments CONTROL, REMINDER, and SOCIAL, covering all users, while the second page of Table 10 reports the results for all five treatments, restricted to previously late users only. For the sake of brevity, we show results for the dependent variable *Proportion Late*, but find similar effects for the dependent variable "Actual-Due" Date.

[Table 10 here]

We start commenting on the treatment effects separated by gender. Whether and why gender matters has increasingly attracted economists' attention, and our data offer a rare opportunity to investigate gender differences in the reaction to the different email treatments. The first page of Table 10 shows that the REMINDER email works somewhat better for men than for women, and the opposite for the SOCIAL. However, the gender differences are statistically insignificant (see the p-values in the third column).

The second page of Table 10 confirms this result for all five treatments. Therefore, women and men are very much comparable when it comes to the reaction to messages aimed at promoting rule compliance.¹⁹

With respect to age, we classify users in four age groups: below 20 years of age, between 20 and 40, between 40 and 60, and above 60. Note that in Table 10 most users belong to the age group between 20 and 40, while other age groups are less represented. The effect is always significant for the main age group, between 20 and 40, and less often for the other age groups. However, we cannot reject the null that the effect is the same for the different four age groups.

Finally, let us turn to nationalities.²⁰ Our database allows us to distinguish between the users' countries of origin. Hence, we can evaluate whether the behavior of users differs by nationality, and whether there are differential reactions to receiving an email. We classify users into 7 geographical areas according to their nationality: (i) Spain, (ii) Northern and Central Europe (Germany, Belgium, Denmark, Finland, Netherlands, Norway, Sweden, Switzerland, Austria), (iii) Southern and Western Europe (France, Italy, Greece, Portugal), (iv) English speaking countries (UK, US, Canada, Ireland, and Australia), (v) Eastern Europe and Russia (Bulgaria, Croatia, Slovakia, Estonia, Hungary, Lithuania, Poland, Rumania, Russia, Czech Republic, Ukraine, Georgia, Armenia), (vi) Latin America (Argentina, Bolivia, Brazil, Colombia, Cuba, Dominican Republic, Ecuador, Guatemala, Honduras, Mexico, Nicaragua, Paraguay, Peru, El Salvador, Uruguay, Venezuela, Chile, Costa Rica, Panama), and (vii) Asia (Philippines, Japan, Nepal, China, India, South Korea). Spain accounts for the vast majority of users (around 70%), followed by Latin America with 19%, Southern and Western Europe with 6%, and at the bottom of the distribution is Asia with 1%.

Table 10 shows that there are remarkable differences in the reaction to the treatments. First, users from English speaking countries react significantly to every single

¹⁹Our results are in line with experimental findings that display a complex picture of gender. For instance, women do not seem to be more social or fairer per se, but it depends on the circumstances (Croson and Gneezy, 2009; Andreoni and Vesterlund, 2001).

²⁰There is sound evidence that nationality is an important determinant of behavior in a variety of settings. Most related to our study, there are interesting nationality differences in the determinants of corruption (Fisman and Miguel, 2007) and cooperation (Herrmann, Thöni and Gächter, 2008; Gächter, Herrmann and Thöni 2010).

treatment. They reduce the proportion of late returns by up to 30 percentage points.²¹ Previously late users from Asia also react significantly, in particular to the treatments REMINDER, LATE and PENALTY. With the exception of Spain, we do not find consistent and significant effects for the other nationality groups.

Furthermore, when comparing the effects found for Spaniards with the effects found for English speaking and Asian countries, controlling for different initial propensities of being late, as well as different reactions depending on prior propensity to be late, we still find that users from English speaking countries and Asian users react significantly more than Spaniards. Therefore, culture seems to influence how much users react to messages targeted at rule compliance.

4 Conclusions

In this paper we study the effect of a very simple, versatile, and virtually costless mechanism, such as sending email messages, on promoting compliance with rules. The study was conducted in the Public Libraries of Barcelona, where compliance with rules means returning items on time. What makes our setting unique is that we observe a large number of users in a daily-life situation, where rules are simple, well-defined, with low attached penalties, and where compliance is perfectly measurable.

Using the methodology of a randomized field experiment, we show that sending email messages helps to promote compliance with rules. A general reminder of the users' duty to comply with the rule is effective in promoting rule compliance. Furthermore, adding other contents to the general reminder, appealing to one's contribution on the functioning of public libraries or identifying users as having been late in the past, do not bring a significant additional increase in rule compliance. Also, the effect seems to be short term but easily replicable when a second wave of emails is sent. Finally, we also find differential treatment effects depending on users' characteristics. First, the email messages affect all users, although they are specially effective on those users who have shown a worse compliance with the rule in the past. Second, we neither find differential treatment effects by gender, nor by age. And third, we do find differential treatment effects depending on nationalities. In particular, users from English

 $^{^{21}}$ Note that this result is not driven by one single country. The same result holds even if we analyze UK/Ireland and US/Canada separately.

speaking countries react more strongly to the email treatments than Spaniards.

TABLE 2
User Randomization into Treatments CONTROL-REMINDER-SOCIAL

Notes: All variables refer to all users, late and non-late, who were active in windows 1 (1 January-15 May) and 2 (1 March-31 July) and to whom the email was delivered. All variables are obtained at the user level for the pre-treatment period. *Male* takes a value of 1 in case of male, *Age* shows the user's age in years, and *Foreign* is a durmy variable taking a value of 1 in the case of Non-Spanish. *Proportion Late* measures the proportion of late returns per user, and "Actual - Due" Date measures the average number of days between the return date and the deadline per user. *Number of Loans* represents the number of loans per user. *Book, CD, DVD* and *Magazine* reflects the user's average share of Books, CD's, DVD's and Magazines. The *P*-Value in the last column is for the F-Test of equality of variable means across all three groups.

TABLE 3 User Randomization into Treatments CRONTOL-REMINDER-SOCIAL-LATE-PENALTY

Notes: All variables refer to the late users who were active in windows 1 (1 January-15 May) and 2 (1 March-31 July) and to whom the email was delivered. All variables are obtained at the user level for the pre-treatment period. Male takes a value of 1 in case of male, Age shows the user's age in years, and Foreign is a dummy variable taking a value of 1 in the case of Non-Spanish. Proportion Late measures the proportion of late returns per user, and "Actual - Due" Date measures the average number of days between the return date and the deadline per user. No. of Loans represents the number of loans per user. Book, CD, DVD and Magazine reflects the user's average share of Books, CD's, DVD's and Magazines. The P Value in the last column is for the F-Test of equality of variable means across all five groups.

TABLE 5 CONTROL-REMINDER-SOCIAL

HO: Reminder=Social=0 (p-Value)0.080.080.030.130.130.100.030.12Notes: Proportion Late measures the proportion of late returns per user, columns (1) to (4), and "Actual - Due" Date measures the average number of days between
the return date and the due date per user, columns (5) to (8). Columns (1) to (3) and (5) to (7) are estimates for the users who are active in the post-treatment period.
Columns (4) and (8) are Intent-to-Treat estimates where users who are not active in the post treatment period have imputed values of 0 for both dependent variables.
See different email messages in Table 1. CD, DVD and Magazine are dummy variables for the item type (omitted category: Book), August, September, October,
November months dummies (omitted category: July), and Age 20-40, Age 40-60 and Age over 60 are age dummies (omitted category: Age under 20). Male takes a
value of 1 in case of non-Spanish, and No. of Loans is the average number of loans per user. Prior Late and Prior "Actual - Due"
in paranthesis. * p<0.0; **; ** p<0.05; *** p<0.01.</th>

Notes: Proportion Late measures the proportion of late returns per user, columns (1) to (4), and "Actual - Due" Date measures the average number of days between the return date and the due date per user, columns (5) to (8). Columns (1) to (3) and (5) to (7) are estimates for the users who are active in the post-treatment period. Columns (4) and (8) are lentent-to-Treat estimates where users who are not active in the post treatment period have imputed values of 0 for both dependent variables. See the different email messages in Table 1. CD, DVD and Magazine are dummy variables for the item type (omitted category: Book), August, September, October, November months dummies (omitted category: July), and Age 20-40, Age 40-60 are age dummies (omitted category: Age under 20). Male takes a value of 1 in case of male, Foreign a value of 1 in case of non-Spanish, and No. of Loans is the average number of loans per user. Prior Late and Prior "Actual - Due" refer to proportion of late returns per user and the average number of days between the return date and the due date, both prior to the treatment. Robust standard errors in paranthesis. * p<0.1; **; ** p<0.05; *** p<0.01.

TABLE 10 (continued) Heterogeneous treatment Effects on Proportion Late: Gender, Age, Nationality

Notes: The table shows heterogeneous treatment effects of Control-Reminder-Social-Late-Penalty for the dependent variable Proportion Late. The sample is split with regard to gender, age and nationalities. The full set of controls is used. See the notes from Tables 5 and 6. Robust standard errors in paranthesis. * p<0.1; **; ** p<0.05; *** p<0.01.
